LEVEL 2: Python for Data Manipulation and Analysis

Day 1

COURSE OUTLINE

- Introduction to Python Programming
- Python Environments
- Data Types and Operations
- Python Data Structures
- Control Flow Statements in Python
- Python Functions
- Python Classes
- NumPy
- Pandas
- Matplotlib

Learning Objectives

- Write basic Python programs and understand Python environments
- Use core data types and data structures effectively
- Control program flow using conditions and loops
- Create reusable code with functions and classes
- Perform numerical computing using NumPy
- Analyze and manipulate data using Pandas
- Visualize data clearly using Matplotlib

Python Programming

Introduction

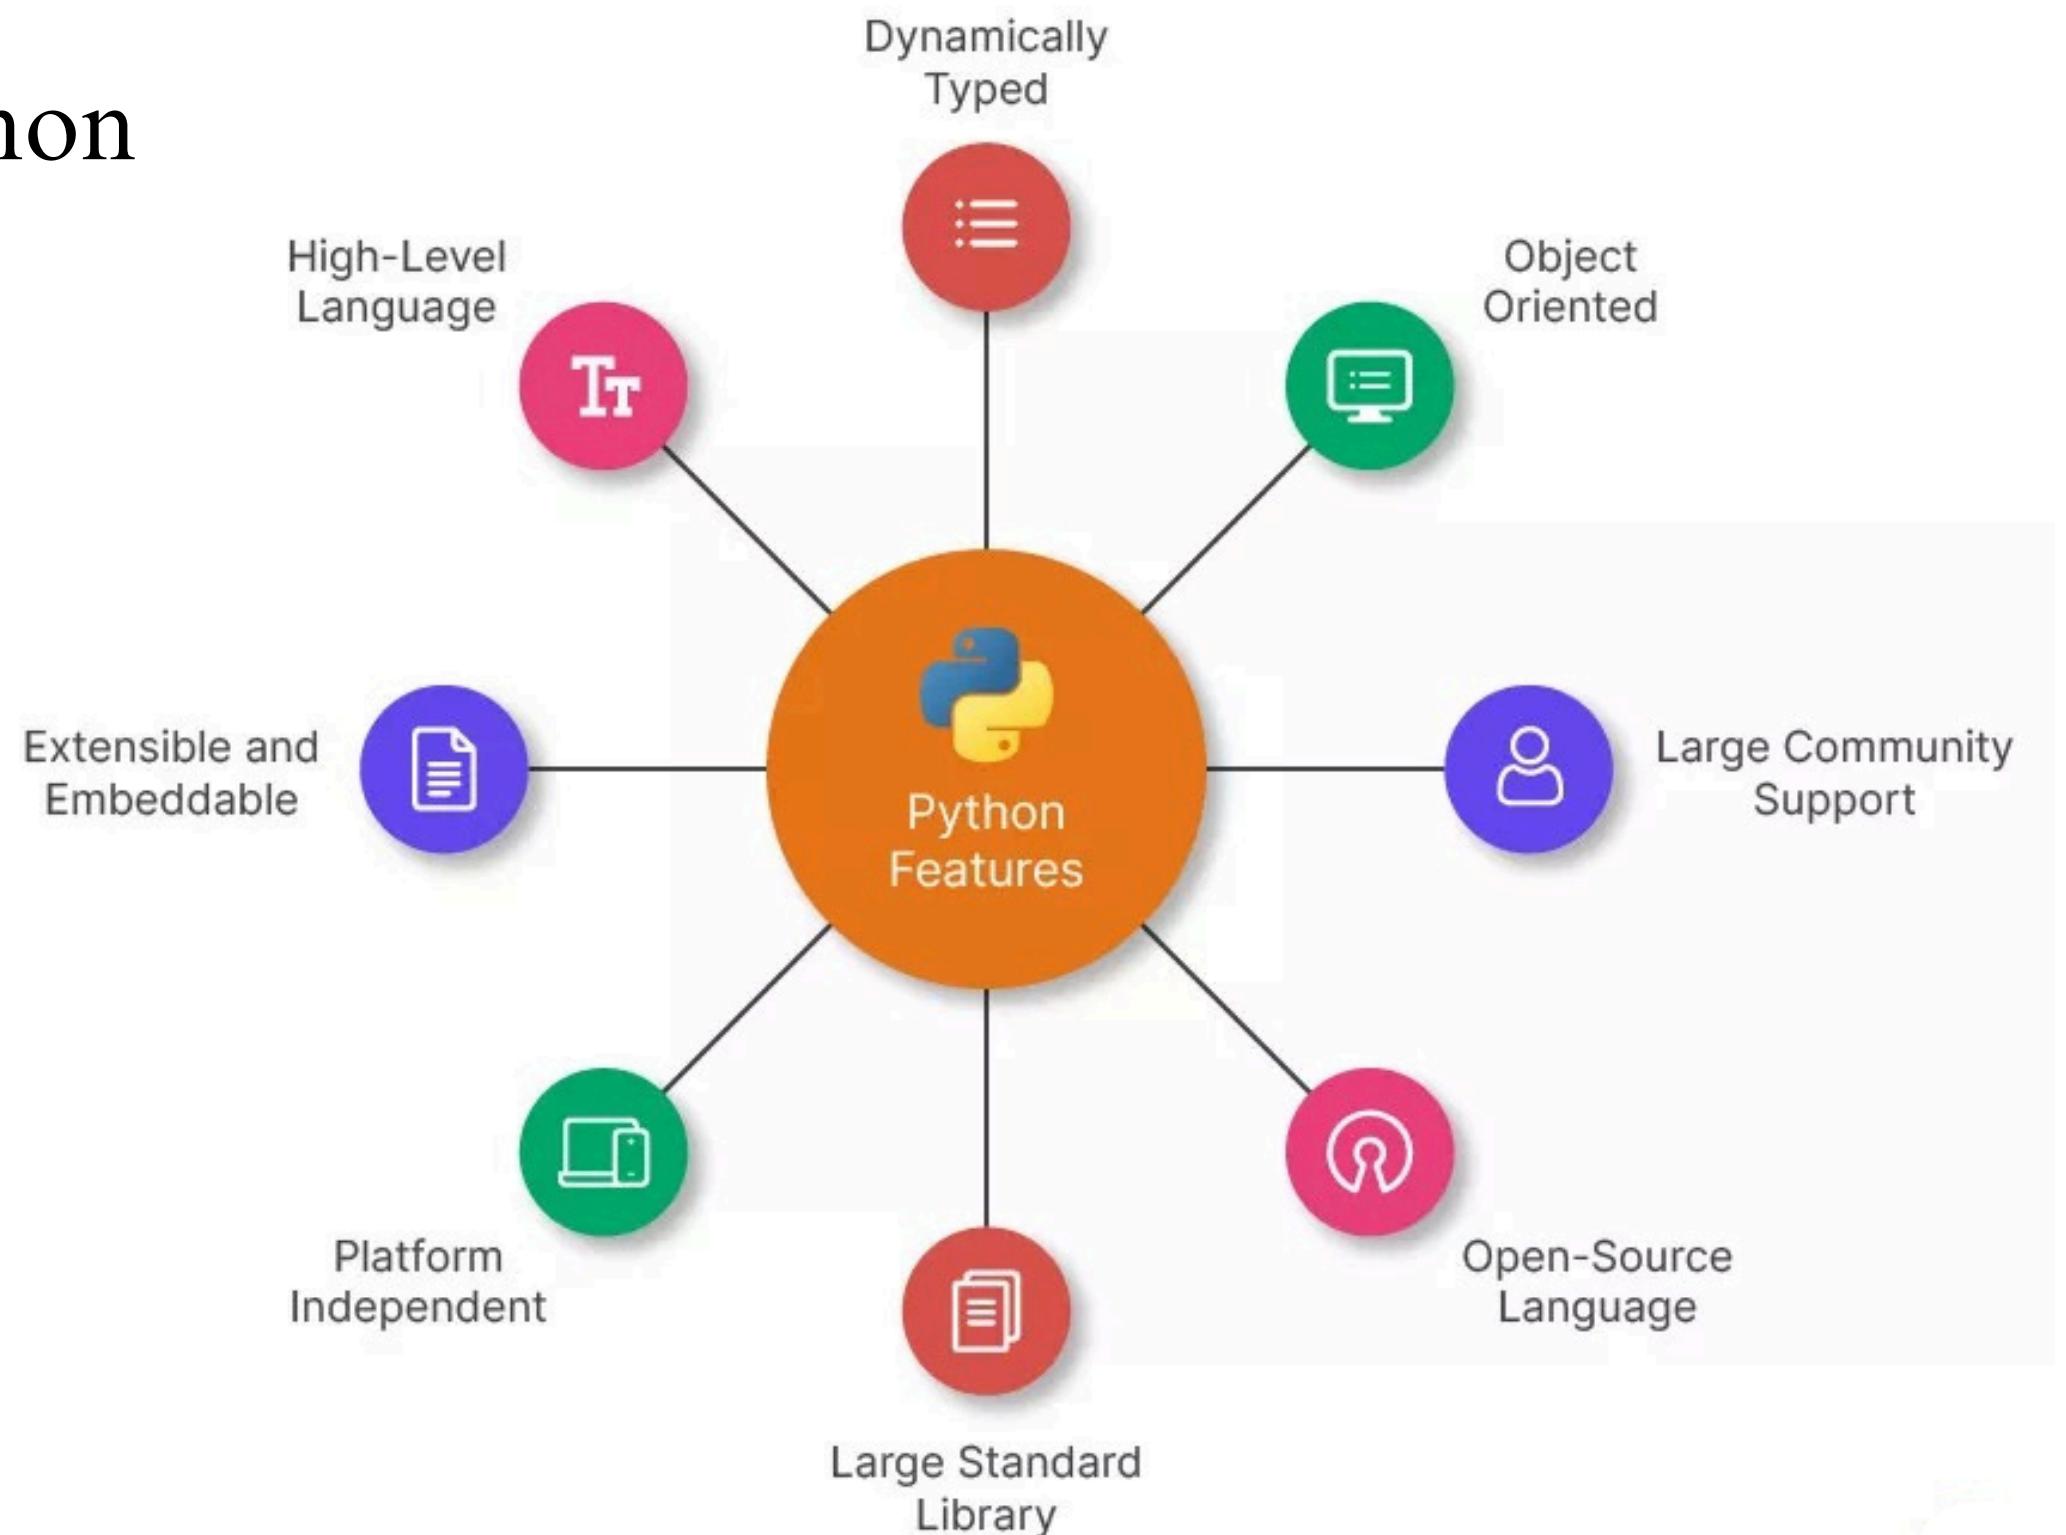

Python Programming

- A high-level, interpreted programming language
- Known for simple, readable syntax
- Enables fast development and high productivity
- Supports modular and reusable code
- Free, open-source, and works across platforms
- Widely used in software development, data science, AI, and automation

Python Programming

> Key Features of Python

*

Python Programming

> Why Python?

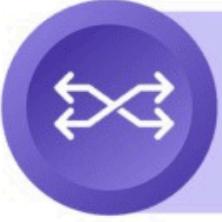

Easy & Simple

Efficient

**Diverse libraries
& framework**

Versatile

Vast community

**Portable
& Extensible**

Flexible

Documentation

*

Python Programming

➤ Why Python Is Ideal for AI & Machine Learning?

➤ Rich AI/ML libraries

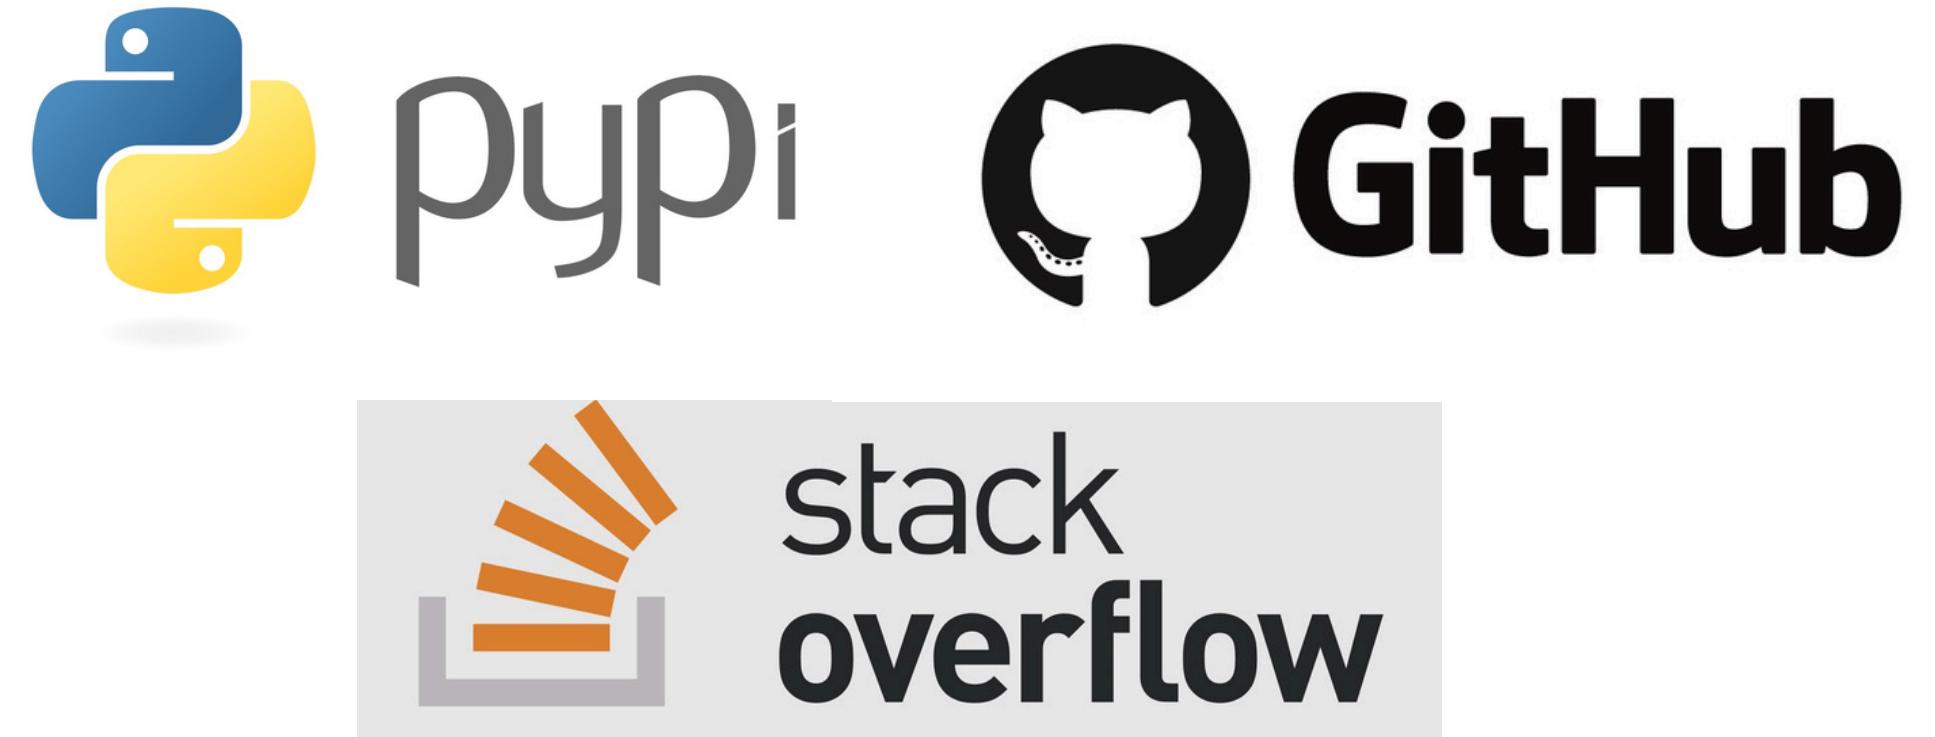

TensorFlow

Python Programming

➤ Why Python Is Ideal for AI & Machine Learning

➤ Strong global community

Python Programming

➤ Why Python Is Ideal for AI & Machine Learning

➤ High Performance

Python Programming

Python Environments

Python Environment

- A Python environment provides an interface for writing and executing Python code, allowing the computer to interpret and run instructions.

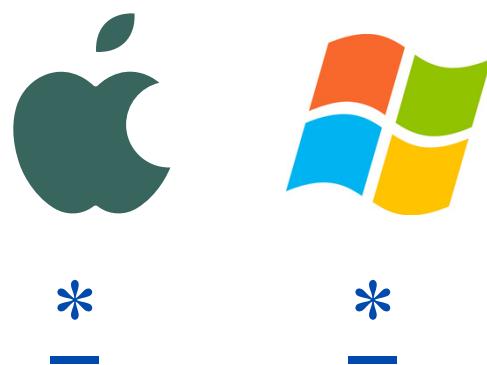

- Google Colab
 - *
 -

Google Colab is a free, cloud-based Python environment that runs in your browser, with no installation required.

Python Environment

- A Python environment provides an interface for writing and executing Python code, allowing the computer to interpret and run instructions.
- Jupyter Notebook

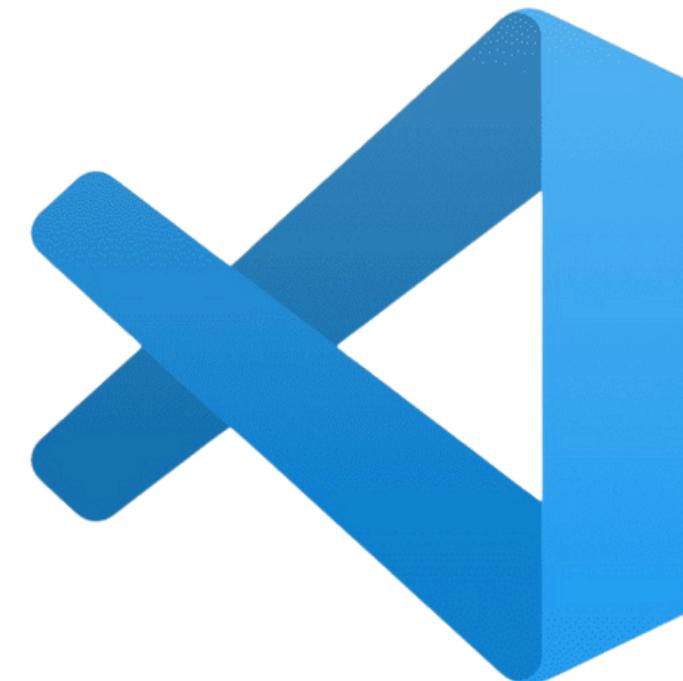

Jupyter Notebook is an interactive, web-based computational environment that enables users to create and share documents containing executable code, narrative text, mathematical equations, and visualizations.

Python Environment

- A Python environment provides an interface for writing and executing Python code, enabling the computer to interpret and run the instructions.

➤ VS Code

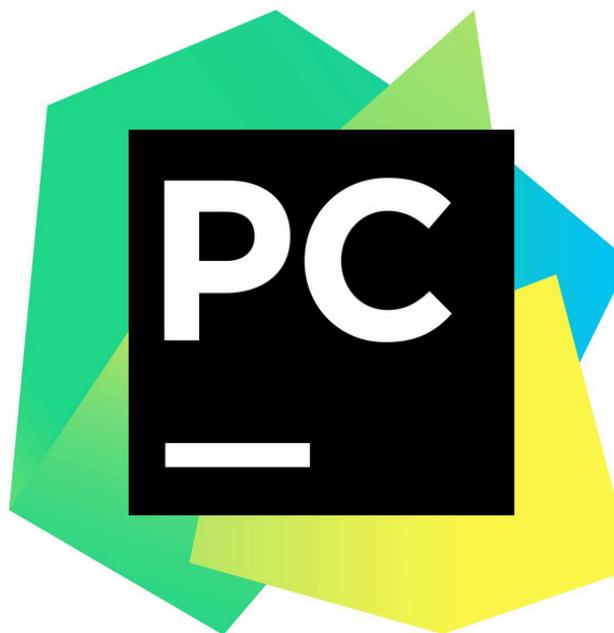

VS Code is a code editor used to write, run, and debug Python programs.

Python Environment

- A Python environment provides an interface for writing and executing Python code, allowing the computer to interpret and run instructions.
 - Other Python Environments

kaggle

Python Programming

Data Types and Operations

Data Types and Operations

➤ Data Types

Category	Data Type	Description	Example
Numeric	int	Whole numbers	10, -3
Numeric	float	Decimal numbers	3.14, -0.5
Numeric	complex	Numbers with real & imaginary parts	2+3j
Text	str	Text (characters)	"Hello"
Boolean	bool	True or False	True, False

Data Types and Operations

➤ Data Types

Category	Data Type	Description	Example
Sequence	list	Ordered, changeable collection	[1, 2, 3]
Sequence	tuple	Ordered, unchangeable collection	(1, 2, 3)
Set	set	Unordered, unique elements	{1, 2, 3}
Mapping	dict	Key–value pairs	{"a": 1}
None	NoneType	Represents no value	None

Data Types and Operations

➤ Arithmetic Operators

Operator	Name	Description	Example	Result
+	Addition	Adds two values	$5 + 3$	8
-	Subtraction	Subtracts one value from another	$7 - 3$	5
*	Multiplication	Multiplies two values	$4 * 3$	12
/	Division	Divides two values	$7 / 3$	2.5
//	Floor Division	Divides and rounds down	$10 // 4$	2
%	Modulus	Returns remainder	$10 \% 4$	2
**	Exponentiation	Raises to a power	$2 ** 3$	8

Data Types and Operations

➤ Comparison Operators

Operator	Description	Example	Result
$= =$	Equal to	$5 == 5$	TRUE
$!=$	Not equal	$5 != 3$	TRUE
$>$	Greater than	$7 > 4$	TRUE
$<$	Less than	$3 < 8$	TRUE
\geq	Greater or equal	$5 \geq 5$	TRUE
\leq	Less or equal	$2 \leq 6$	TRUE

Data Types and Operations

➤ Logical Operators

Operator	Name	Example	Result
and	Logical AND	$(5 > 3) \text{ and } (2 < 4)$	TRUE
or	Logical OR	$(5 > 3) \text{ or } (2 > 4)$	TRUE
not	Logical NOT	<code>not (5 > 3)</code>	FALSE

Data Types and Operations

➤ Assignment Operators

Operator	Description	Example	Equivalent
<code>=</code>	Assign	<code>x = 5</code>	<code>x = 5</code>
<code>+=</code>	Add & assign	<code>x += 3</code>	<code>x = x + 3</code>
<code>-=</code>	Subtract & assign	<code>x -= 2</code>	<code>x = x - 2</code>
<code>*=</code>	Multiply & assign	<code>x *= 4</code>	<code>x = x * 4</code>
<code>/=</code>	Divide & assign	<code>x /= 2</code>	<code>x = x / 2</code>

Data Types and Operations

➤ Membership Operators

Operator	Description	Example	Result
in	Value exists	3 in [1,2,3]	TRUE
not in	Value not exists	5 not in [1,2,3]	TRUE

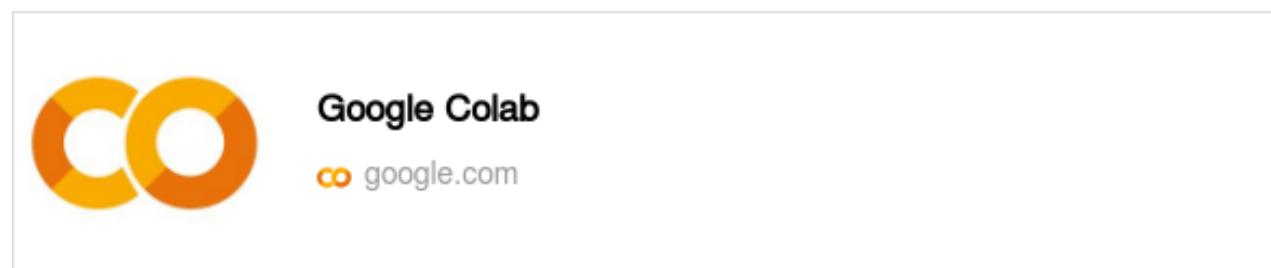

Data Types and Operations

➤ Identity Operators

Operator	Description	Example	Result
is	Same object	a is b	True/False
is not	Different object	a is not b	True/False

Data Types and Operations

> [01-numbers.ipynb](#)

Data Types and Operations

- A string is a sequence of characters
- Used to represent text
- Defined using quotes
 - Double quotes " "
 - Single quotes '

```
city = "Riyadh"  
country = 'Saudi Arabia'
```

Data Types and Operations

- Each character has a position (index)
- Indexing starts from 0

```
text = "Python"  
text[0] # 'P'  
text[3] # 'h'
```

- String Slicing

```
name = "Mohammed"  
name[0:4] # 'Moha'  
name[4:] # 'mmed'
```

Data Types and Operations

> String Concatenation

```
first = "Mohammed"  
last = "Ali"  
full_name = first + " " + last
```

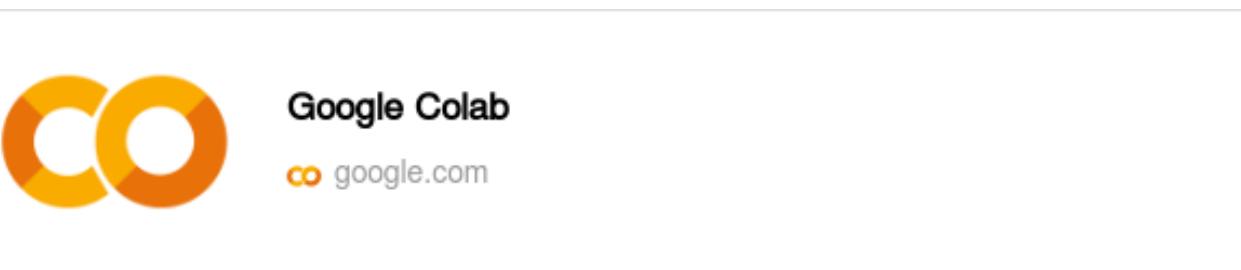

> String Repetition

```
name = "Riyadh"  
name * 3
```

Data Types and Operations

> [02-Strings.ipynb](#)

Python Programming

Python Data Structures

Python Data Structures

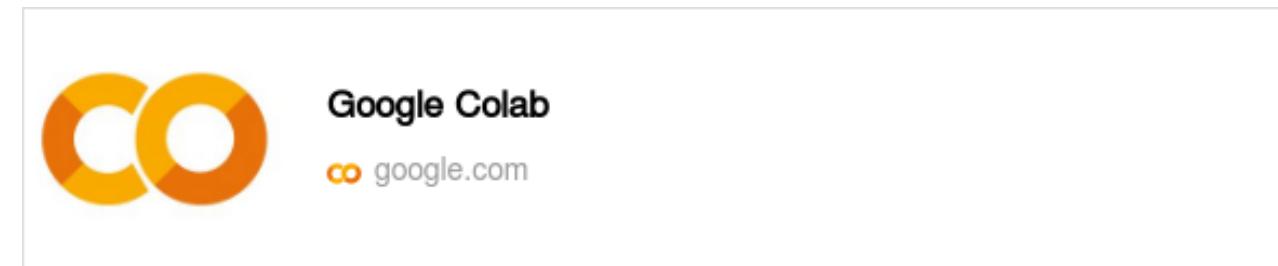

> Lists

- A list is an ordered collection of items
- Lists can store multiple values
- Lists are mutable (can be changed)
- Lists are created using square brackets [].

```
cities = ["Riyadh", "Jeddah", "Dammam"]
```

Python Data Structures

> [03-Lists.ipynb](#)

Python Data Structures

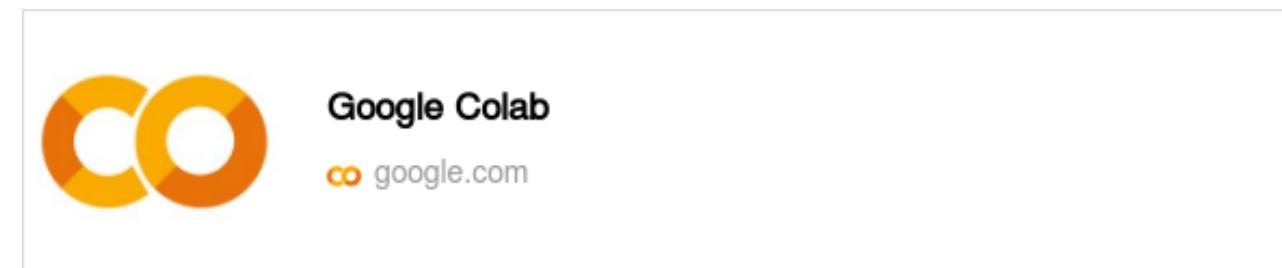

> Dictionaries

- A dictionary stores data as key–value pairs
- Each key maps to a value
- Dictionaries are mutable
- Dictionaries use curly braces {}

```
student = {  
    "name": "Mohammed",  
    "age": 21,  
    "city": "Riyadh"  
}
```

Python Data Structures

> [04-Dictionaries.ipynb](#)

Python Data Structures

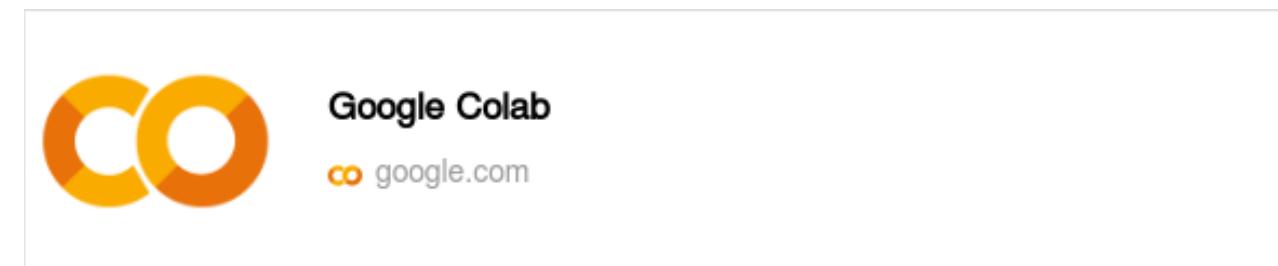

> Tuple

- A tuple is an ordered collection of items
- Tuples are immutable (cannot be changed)
- Used for fixed data

```
person = ("Mohammed", 21, "Riyadh")
```

Python Data Structures

> [05-Tuples.ipynb](#)

Python Data Structures

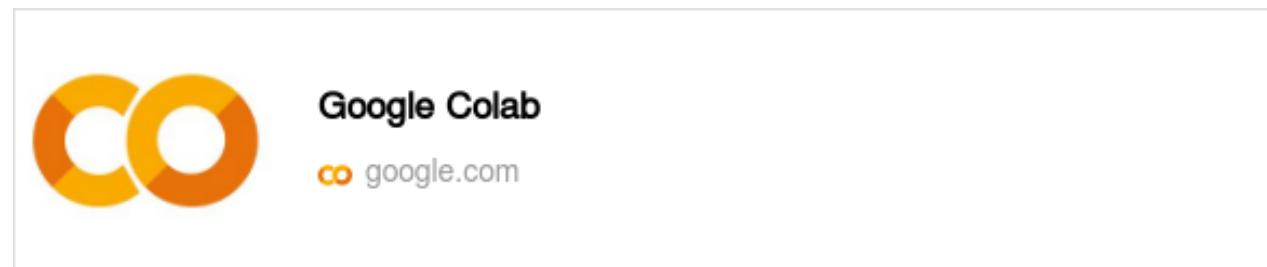

> Set

- A set is an unordered collection of unique elements
- Duplicate values are automatically removed
- Uses curly braces {}
- Sets are mutable

```
numbers = {1, 2, 3}  
empty_set = set() # not {}
```

Python Data Structures

> [06-Sets.ipynb](#)

Python Data Structures

Data Structure	Syntax	Ordered	Mutable	Allows Duplicates	Access Method	Common Use Case
List	[]	Yes	Yes	Yes	Index	Store and modify collections of items
Tuple	()	Yes	No	Yes	Index	Store fixed, unchangeable data
Set	{ }	No	Yes	No	Membership (in)	Remove duplicates, fast lookup
Dictionary	{key: value}	Yes*	Yes	(keys)	Key	Store structured data (records)

* Dictionaries are ordered from Python 3.7+

Python Programming

Control Flow Statements in Python

Control Flow Statements in Python

> if

- if is a conditional statement
- It is used to make decisions in code
- Code runs only if the condition is True

```
score = 75
if score >= 60:
    print("Pass")
```

Control Flow Statements in Python

> if with else

```
city = "Riyadh"

if city == "Riyadh":
    print("Welcome to the capital")
else:
    print("Welcome")
```

Control Flow Statements in Python

> if, elif, else

```
score = 85

if score >= 90:
    print("Excellent")
elif score >= 70:
    print("Good")
else:
    print("Needs improvement")
```

Control Flow Statements in Python

➤ Indentation Is Important

- Python uses indentation, not { }

➤ Common Mistakes

Using = instead of ==

Forgetting indentation

Missing : at the end of if

```
if True:  
    print("Correct")
```

```
# if True:  
#     print("Error")
```

Control Flow Statements in Python

> for Loop

- A for loop is used to repeat actions
- It iterates over a sequence (list, string, range, etc.)
- Executes the block once per item

```
for i in range(5):  
    print(i)
```

```
1,2,3,4,5
```

Control Flow Statements in Python

> for with if

```
scores = [95, 72, 40]
```

```
for score in scores:  
    if score >= 60:  
        print(score, "Pass")  
    else:  
        print(score, "Fail")
```

95 Pass
72 Pass
40 Fail

Control Flow Statements in Python

> while loops

- A while loop repeats code as long as a condition is True
- The condition is checked before each iteration

```
count = 0

while count < 5:
    print(count)
    count += 1
```

> Common Mistakes

- Forgetting to update the condition variable
- Infinite loops
- Missing indentation

Control Flow Statements in Python

> while loops

- Infinite Loop

∞

```
while True:  
    print("This runs forever")
```

- Using break

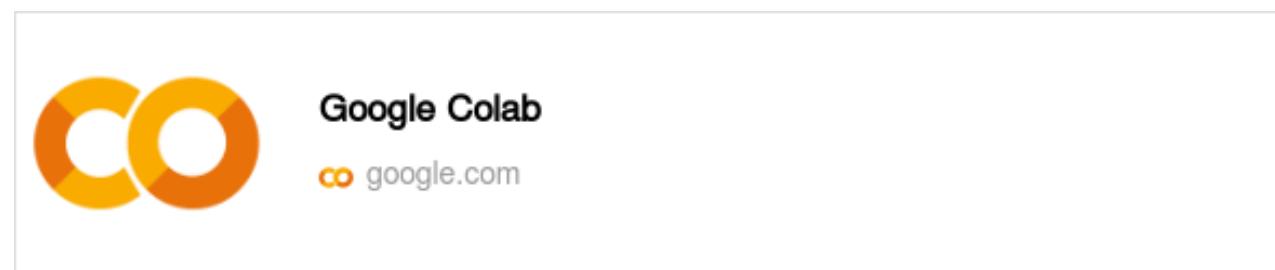

```
while True:  
    user_input = input("Type 'exit' to stop: ")  
    if user_input == "exit":  
        break
```

Control Flow Statements in Python

Statement	Purpose	When to Use	Typical Example
if	Decision making	When you need to choose between actions	Pass / Fail
for	Iteration	When number of iterations is known	Loop through a list
while	Conditional looping	When repetitions depend on a condition	User input loop

Control Flow Statements in Python

> [07-Control Flow.ipynb](#)

Python Programming

Python Functions

Python Functions

> Functions

- `def` → defines a function
- Function name follows naming rules
- Code block is indented

- Function Syntax

```
def greet():  
    print("Hello!")
```

- Calling a Function

```
greet()
```

* Function runs only when called

Python Functions

> Function with Parameters

- Function Syntax

```
def greet(name):  
    print("Hello", name)
```

- Calling a Function

```
greet("Mohammed")
```

> Multiple Parameters

- Function Syntax

```
def add(a, b):  
    print(a + b)
```

- Calling a Function

```
add(3, 5)
```

Python Functions

> Returning Values

- Function Syntax

```
def add(a, b):  
    return a + b
```

- Calling a Function

```
result = add(4, 6)  
print(result)
```

*Return sends a value back

print	return
Displays output	Sends value back
Used for display	Used for logic
Returns None	Returns data

Python Programming

Python Classes

Python Classes

> Class

- A class is a blueprint for creating objects
- It groups data (attributes) and functions (methods)
- Used to model real-world entities

- Class

```
class Student:  
    name = "Mohammed"  
    age = 21
```

- Object (Instance)

```
s1 = Student()  
print(s1.name)  
print(s1.age)
```

Python Classes

> The `__init__` Method (Constructor)

- Class

```
class Student:  
    def __init__(self, name, age):  
        self.name = name  
        self.age = age
```

- Object (Instance)

```
s1 = Student("Ali", 20)  
s2 = Student("Sara", 22)
```

- Runs automatically when the object is created
- `self` refers to the current object

Python Classes

> Instance Attributes

```
print(s1.name)  
print(s1.age)
```

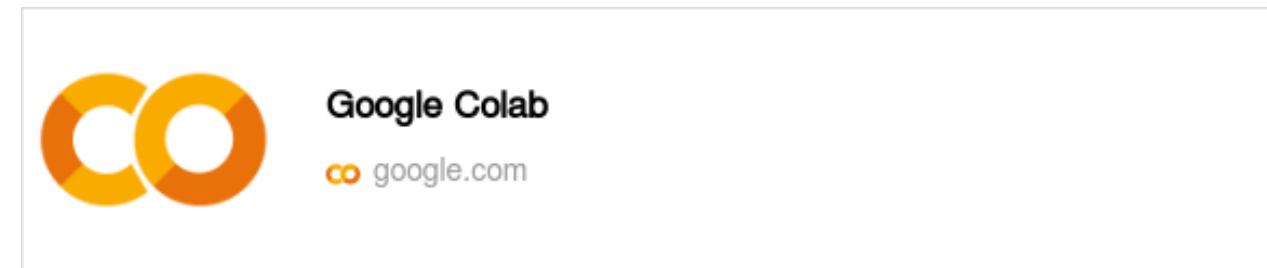

> Methods (Functions Inside a Class)

```
class Student:  
    def greet(self):  
        print("Hello, my name is", self.name)
```

```
s1.greet()
```

Python Programming

NumPy

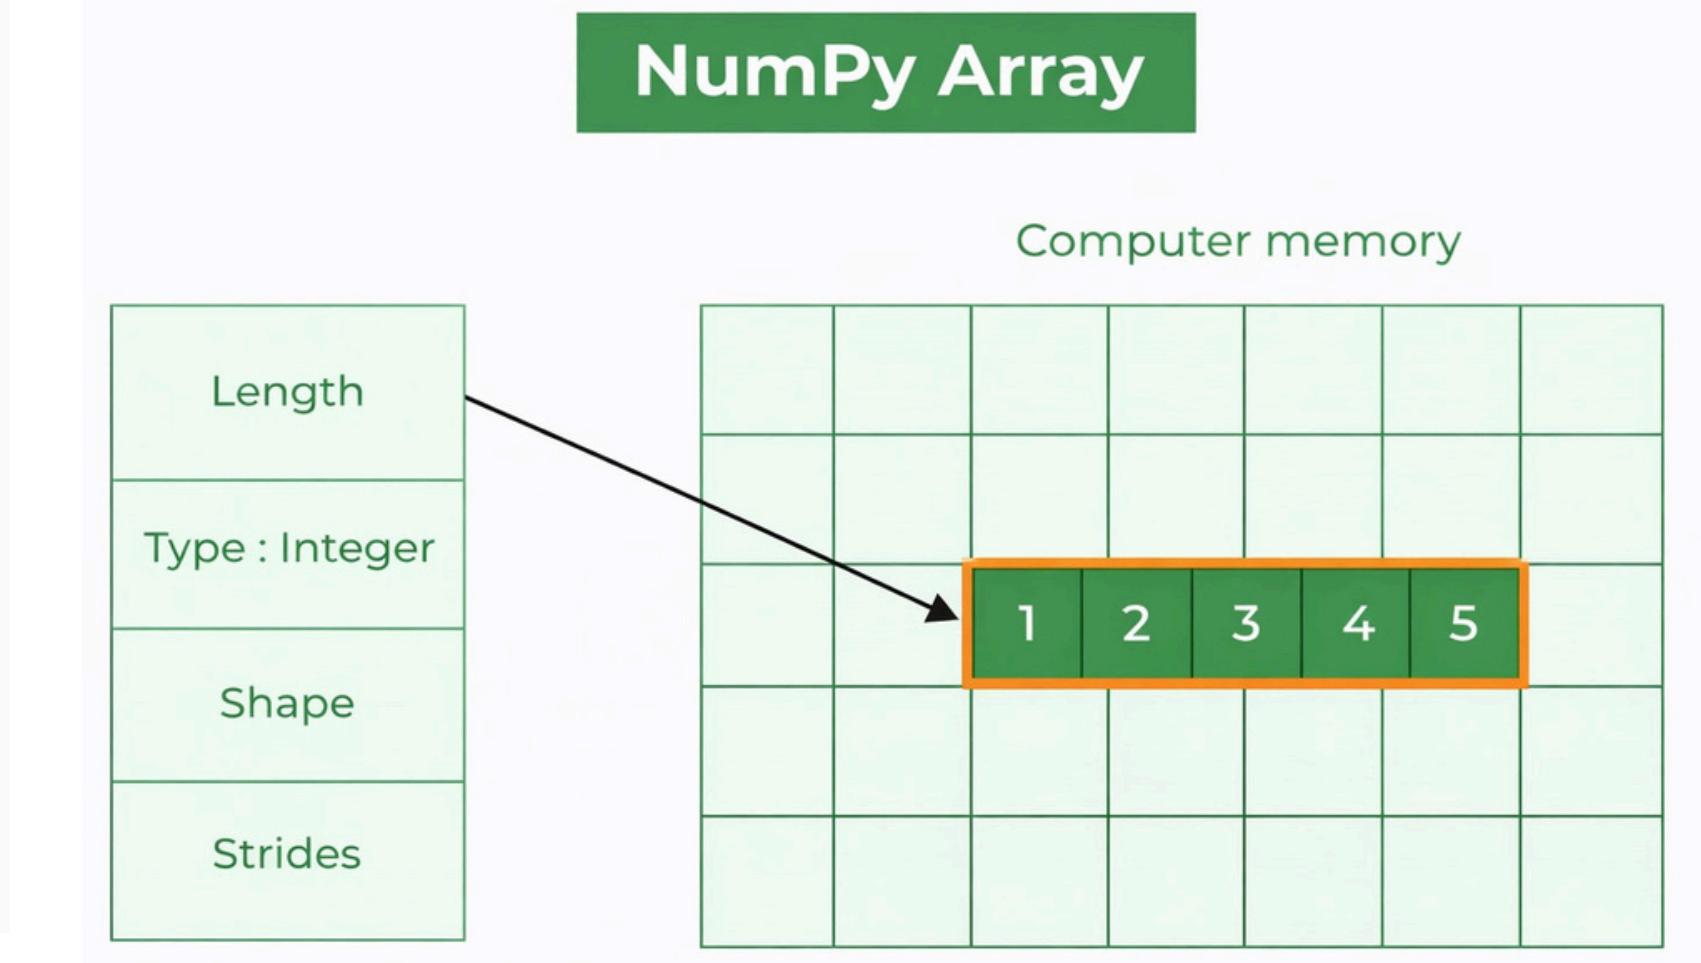

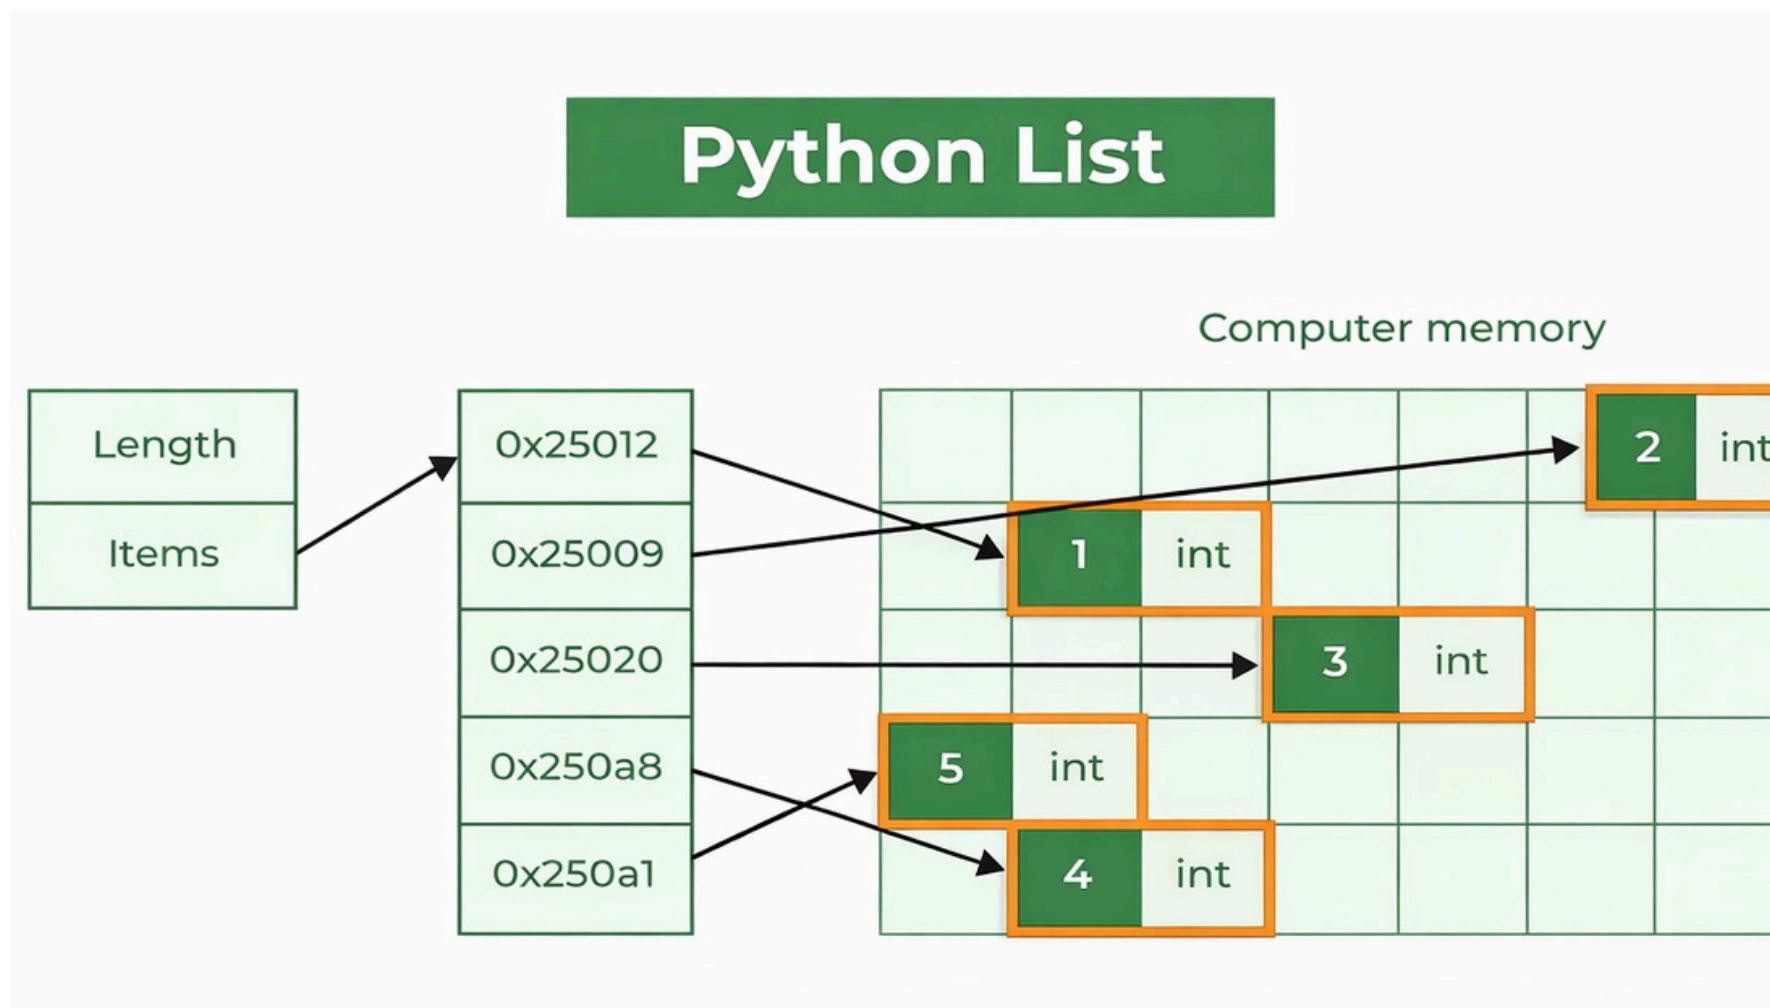

NumPy

- NumPy is a Python library for numerical computing
- It provides fast, efficient array operations
- Widely used in data science, ML, and scientific computing

NumPy

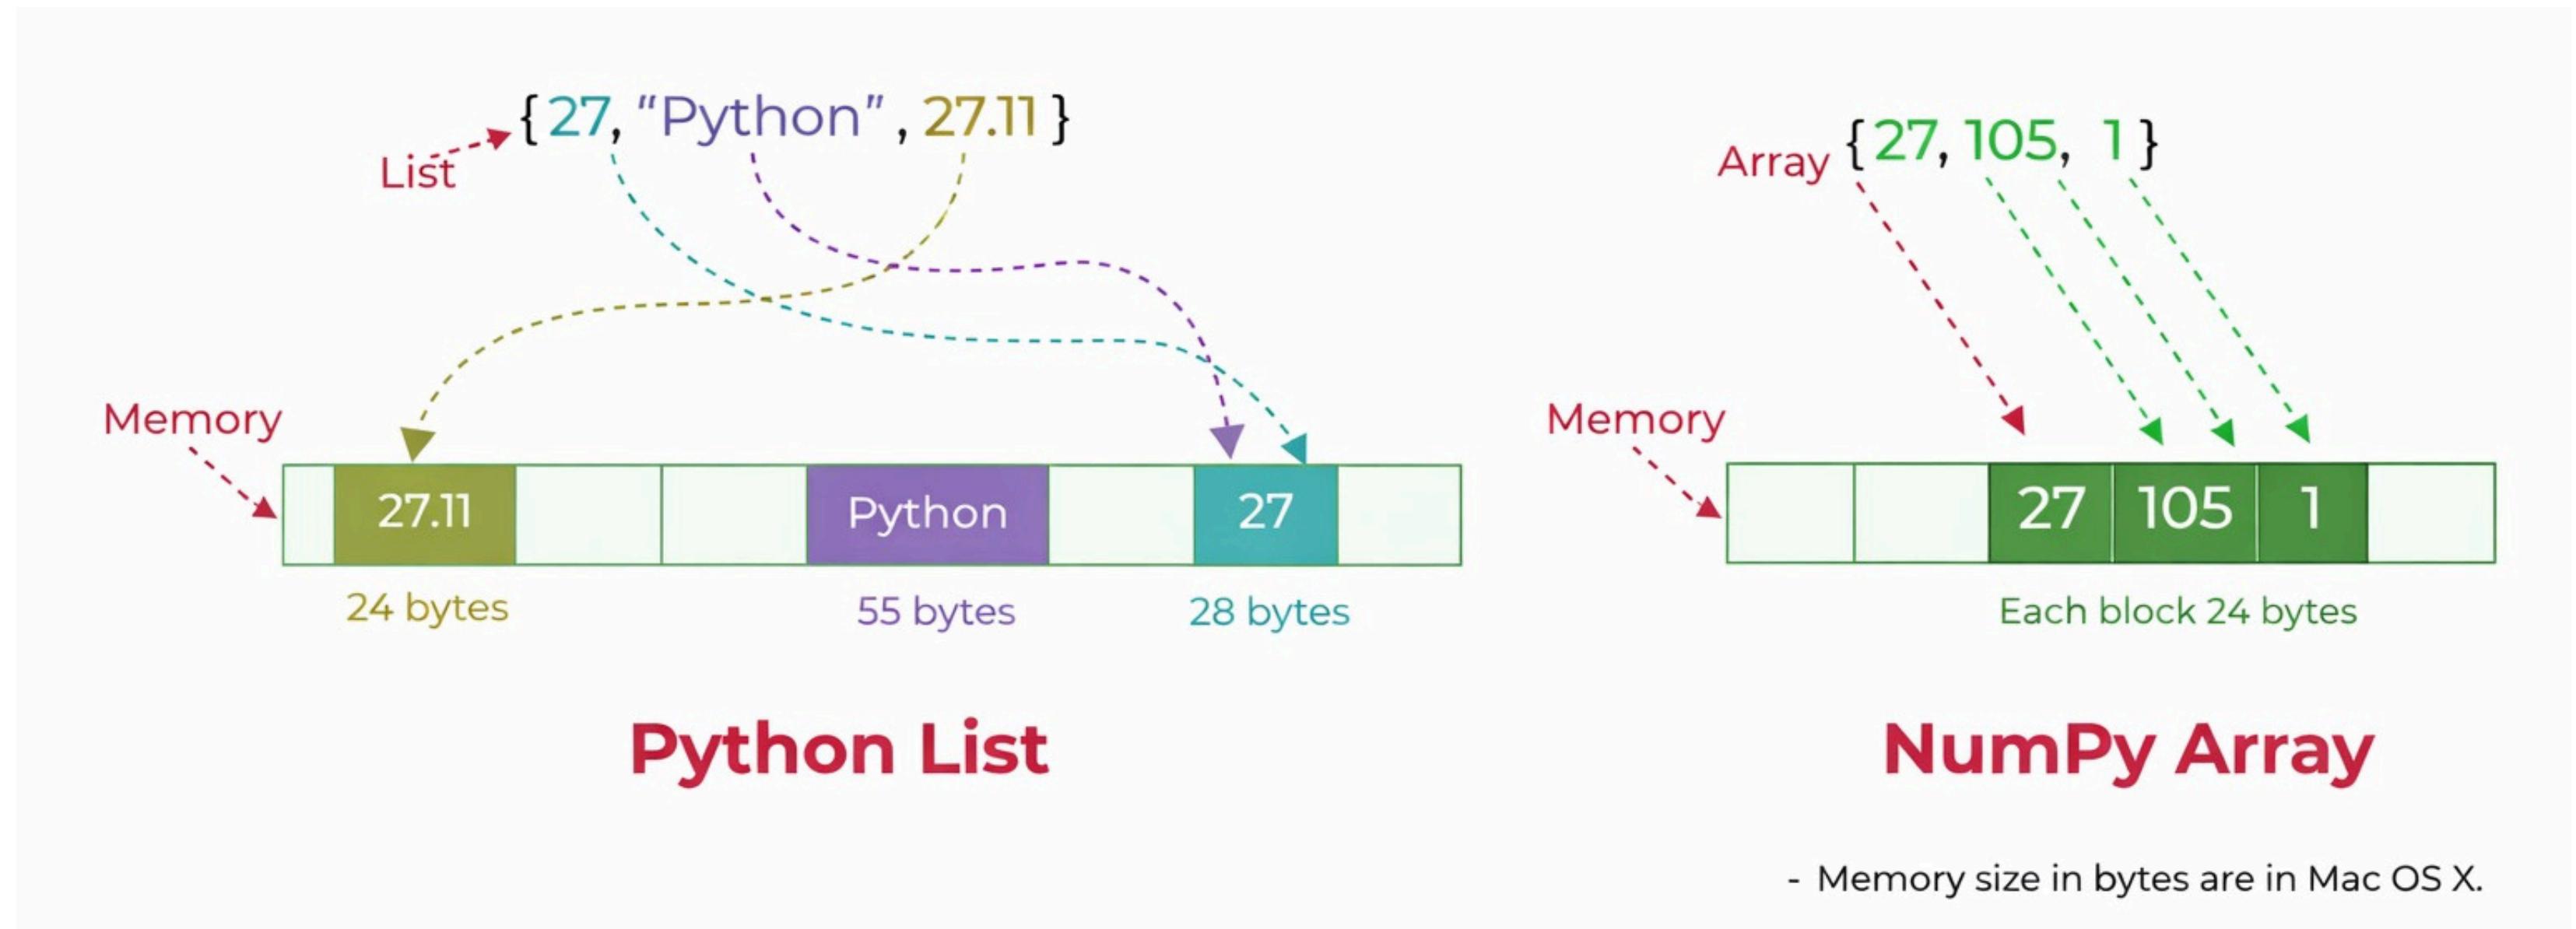

- Python Lists VS Numpy Arrays

*

NumPy

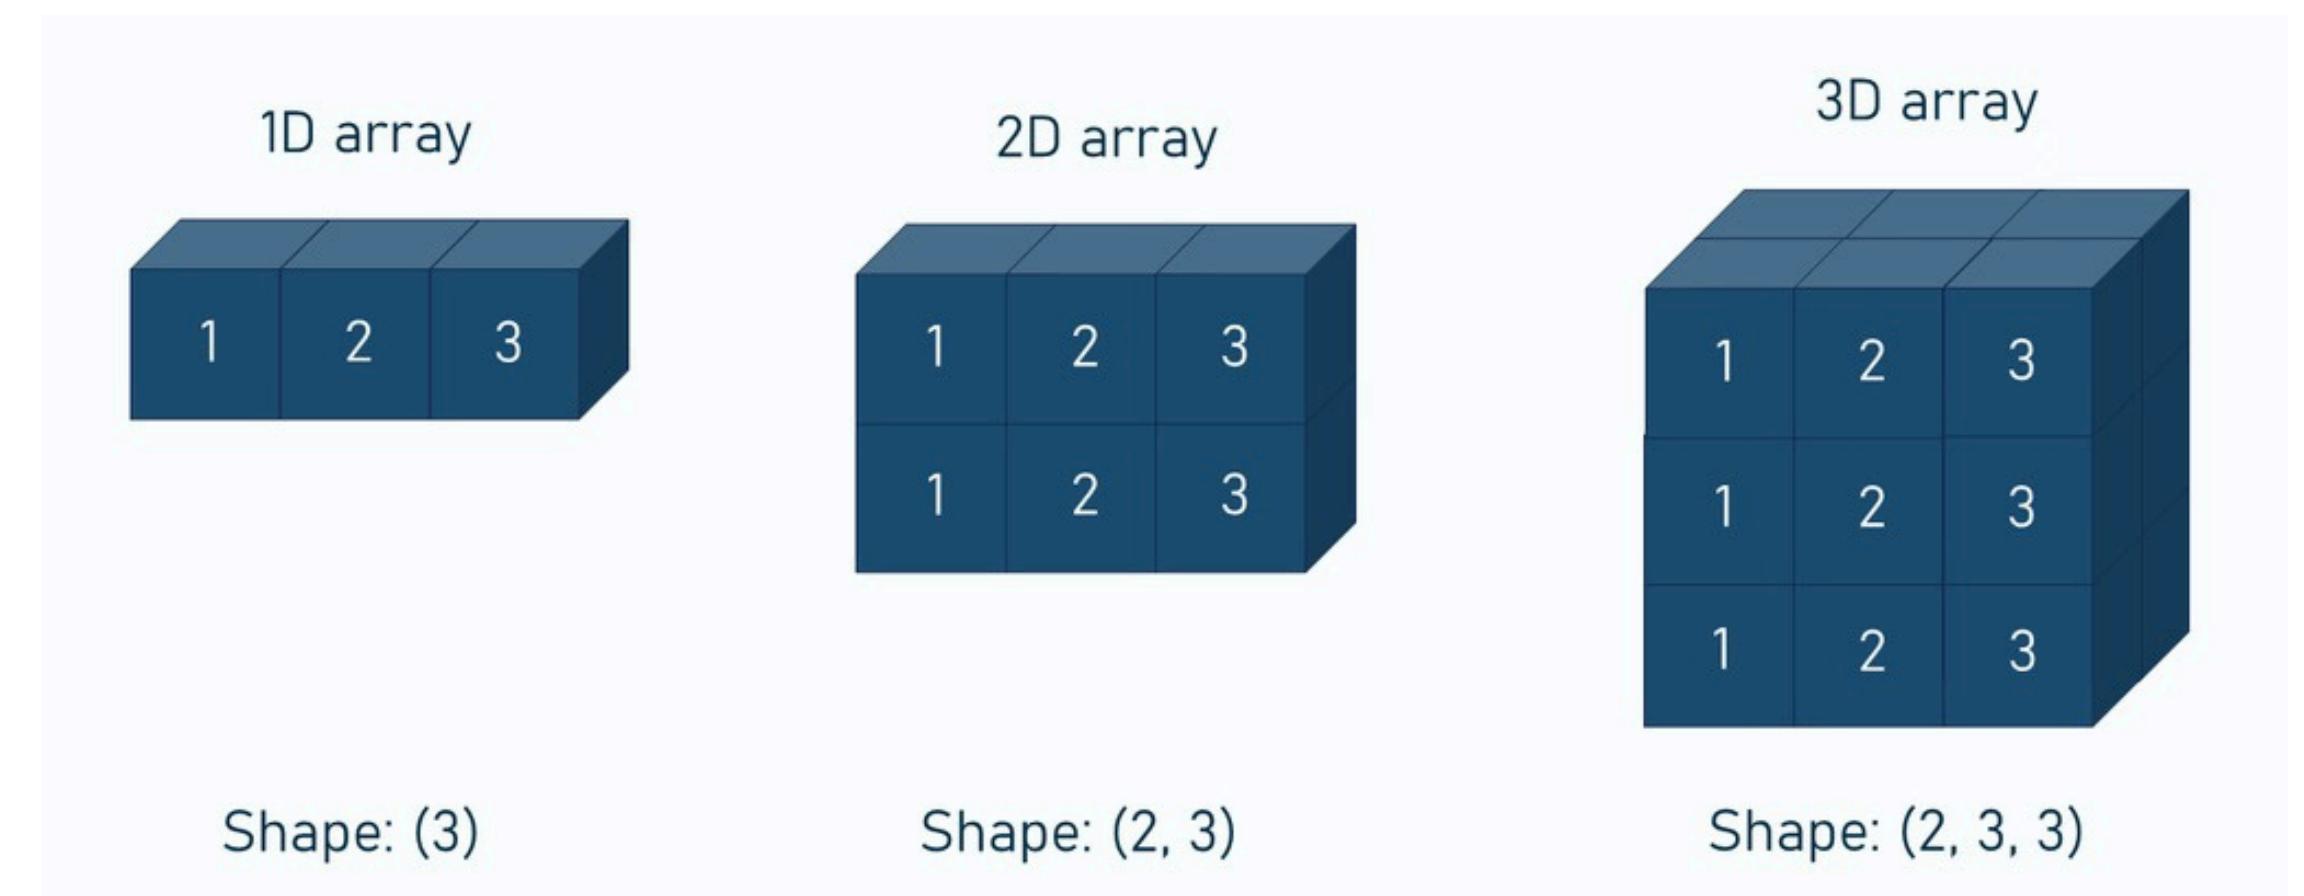

- Python Lists VS Numpy Arrays

NumPy

- NumPy Arrays

```
</>  
np.array([1, 2, 3, 4])
```

NumPy

- Arrays filled with values

```
np.zeros(5)  
np.ones((2, 3))
```

- Random Arrays

```
np.random.rand(3)  
np.random.randn(2, 2)
```

- Sequences of numbers

```
np.arange(0, 10, 2)  
np.linspace(0, 1, 5)
```

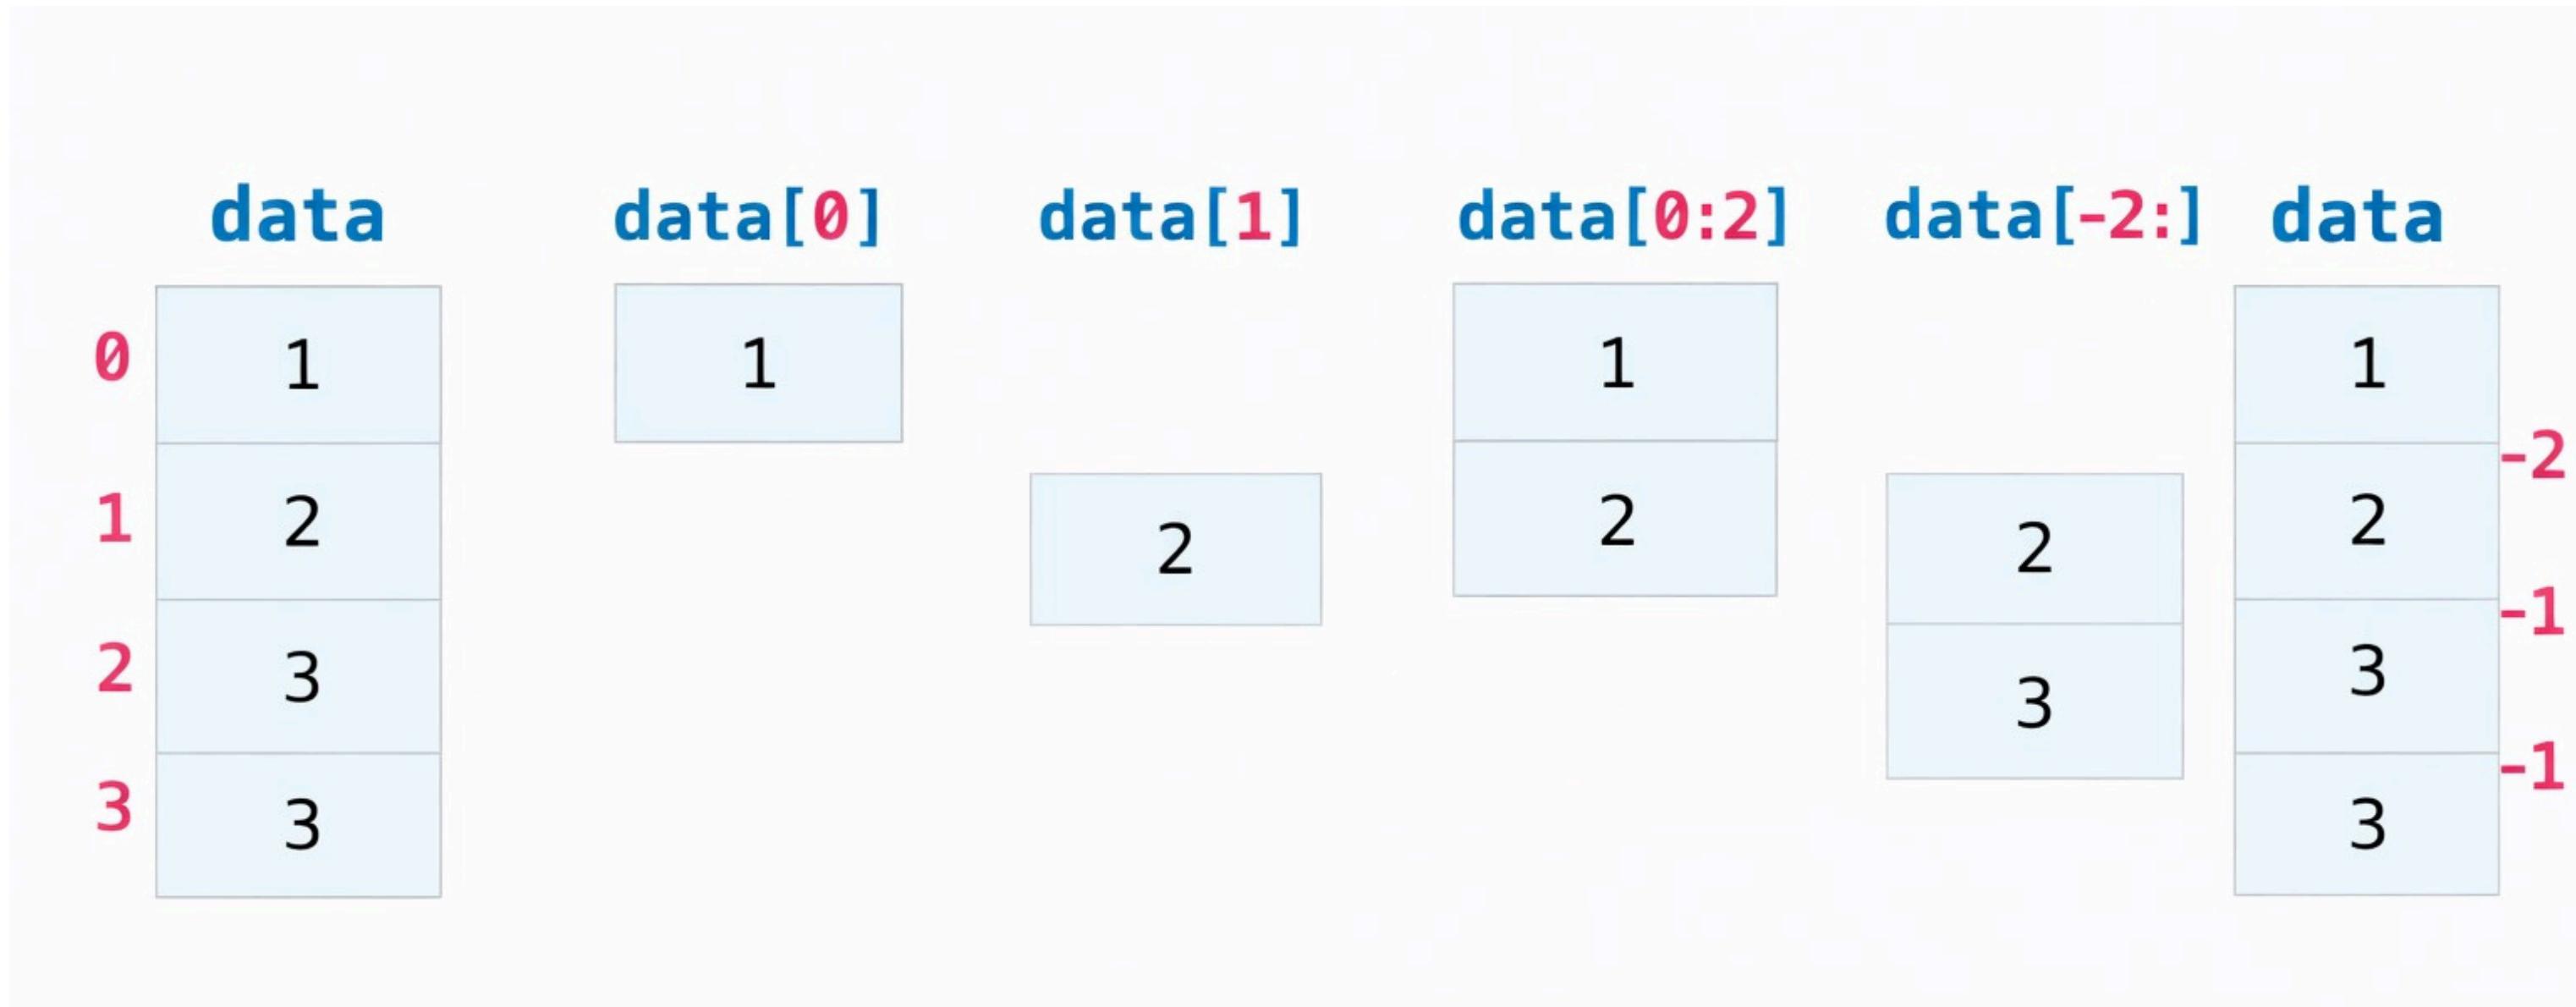

- dtype

```
np.array([1, 2, 3]).dtype
```

NumPy

> Indexing and slicing

NumPy

> Array operations

```
data = np.array([1,2])
```

data

1

Pandas

> Creating a DataFrame

```
pd.DataFrame({"A": [1, 2], "B": [3, 4]})
```

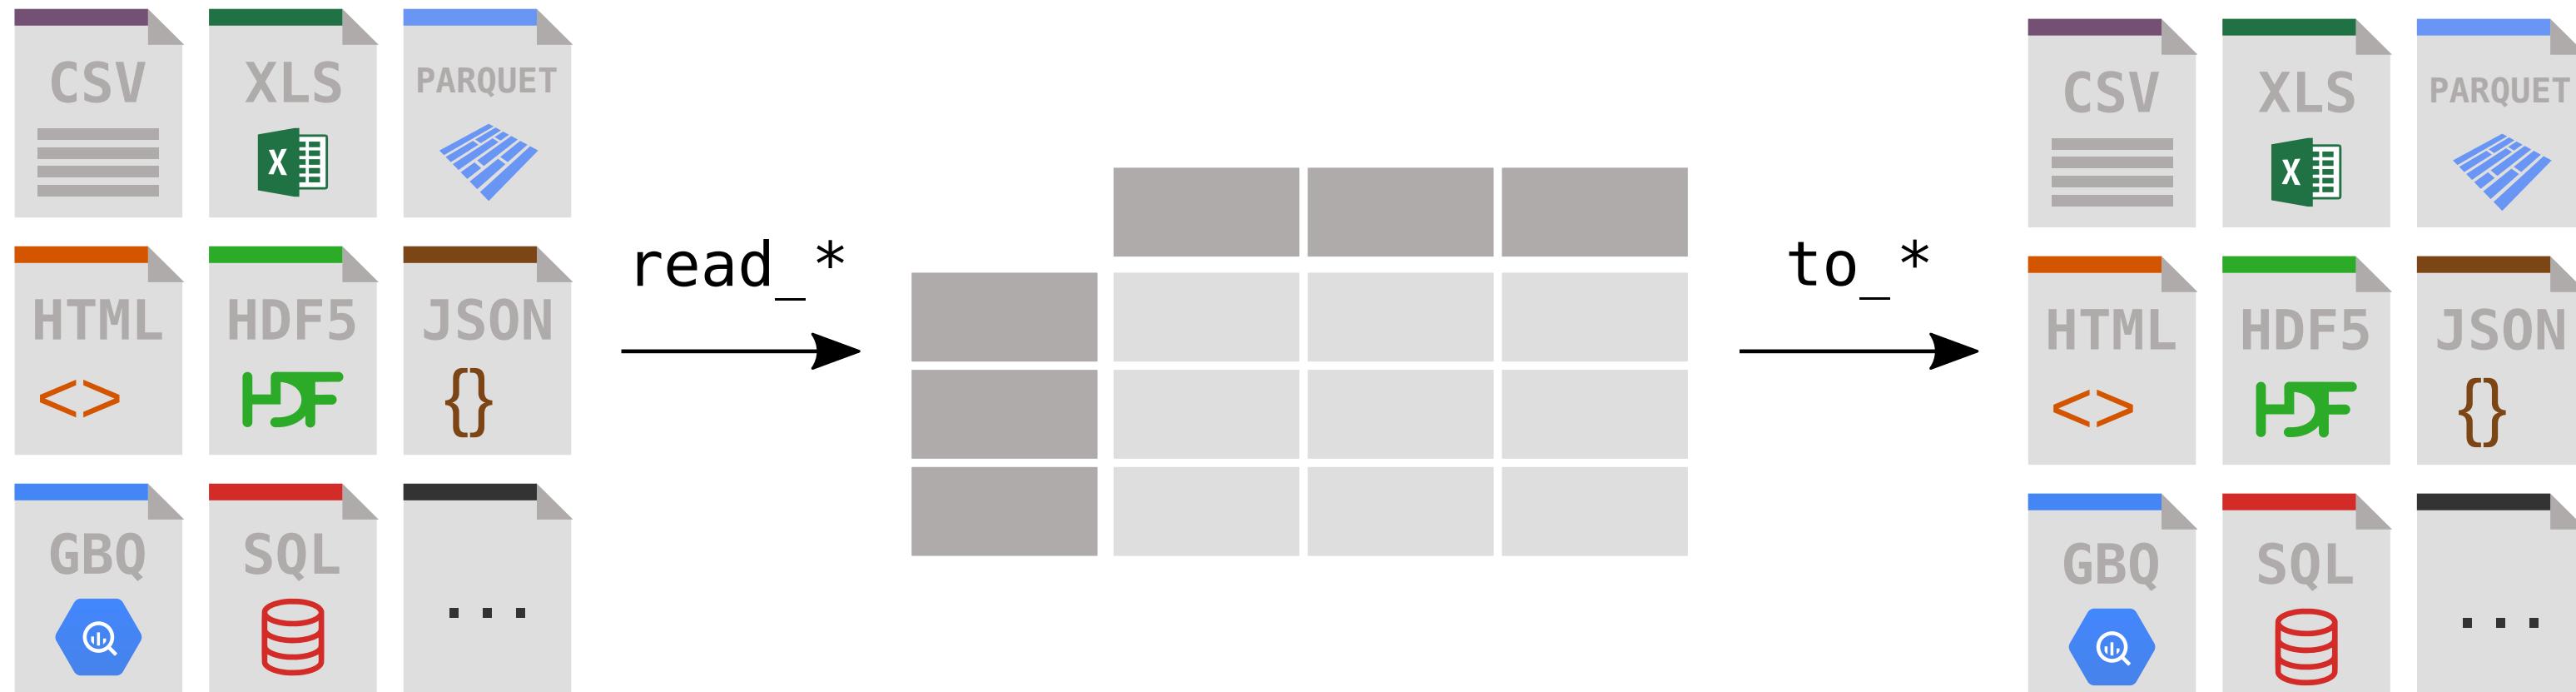

```
pd.DataFrame(np.array([[1, 2], [3, 4]]))
```

```
pd.DataFrame([[1, 2], [3, 4]], columns=["A", "B"])
```

```
pd.DataFrame(np.array([[1, 2], [3, 4]]))
```

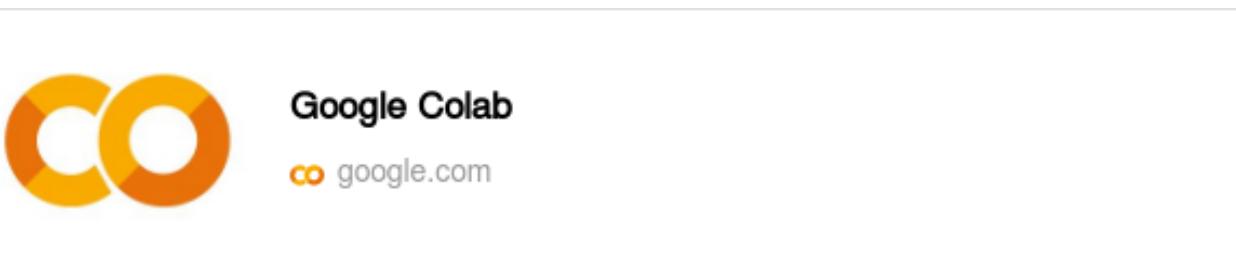

Pandas

➤ Reading Data and Exporting Data

Pandas

> [10-Pandas.ipynb](#)

Python Programming

Matplotlib

Matplotlib

➤ Matplotlib is a Python library for data visualization

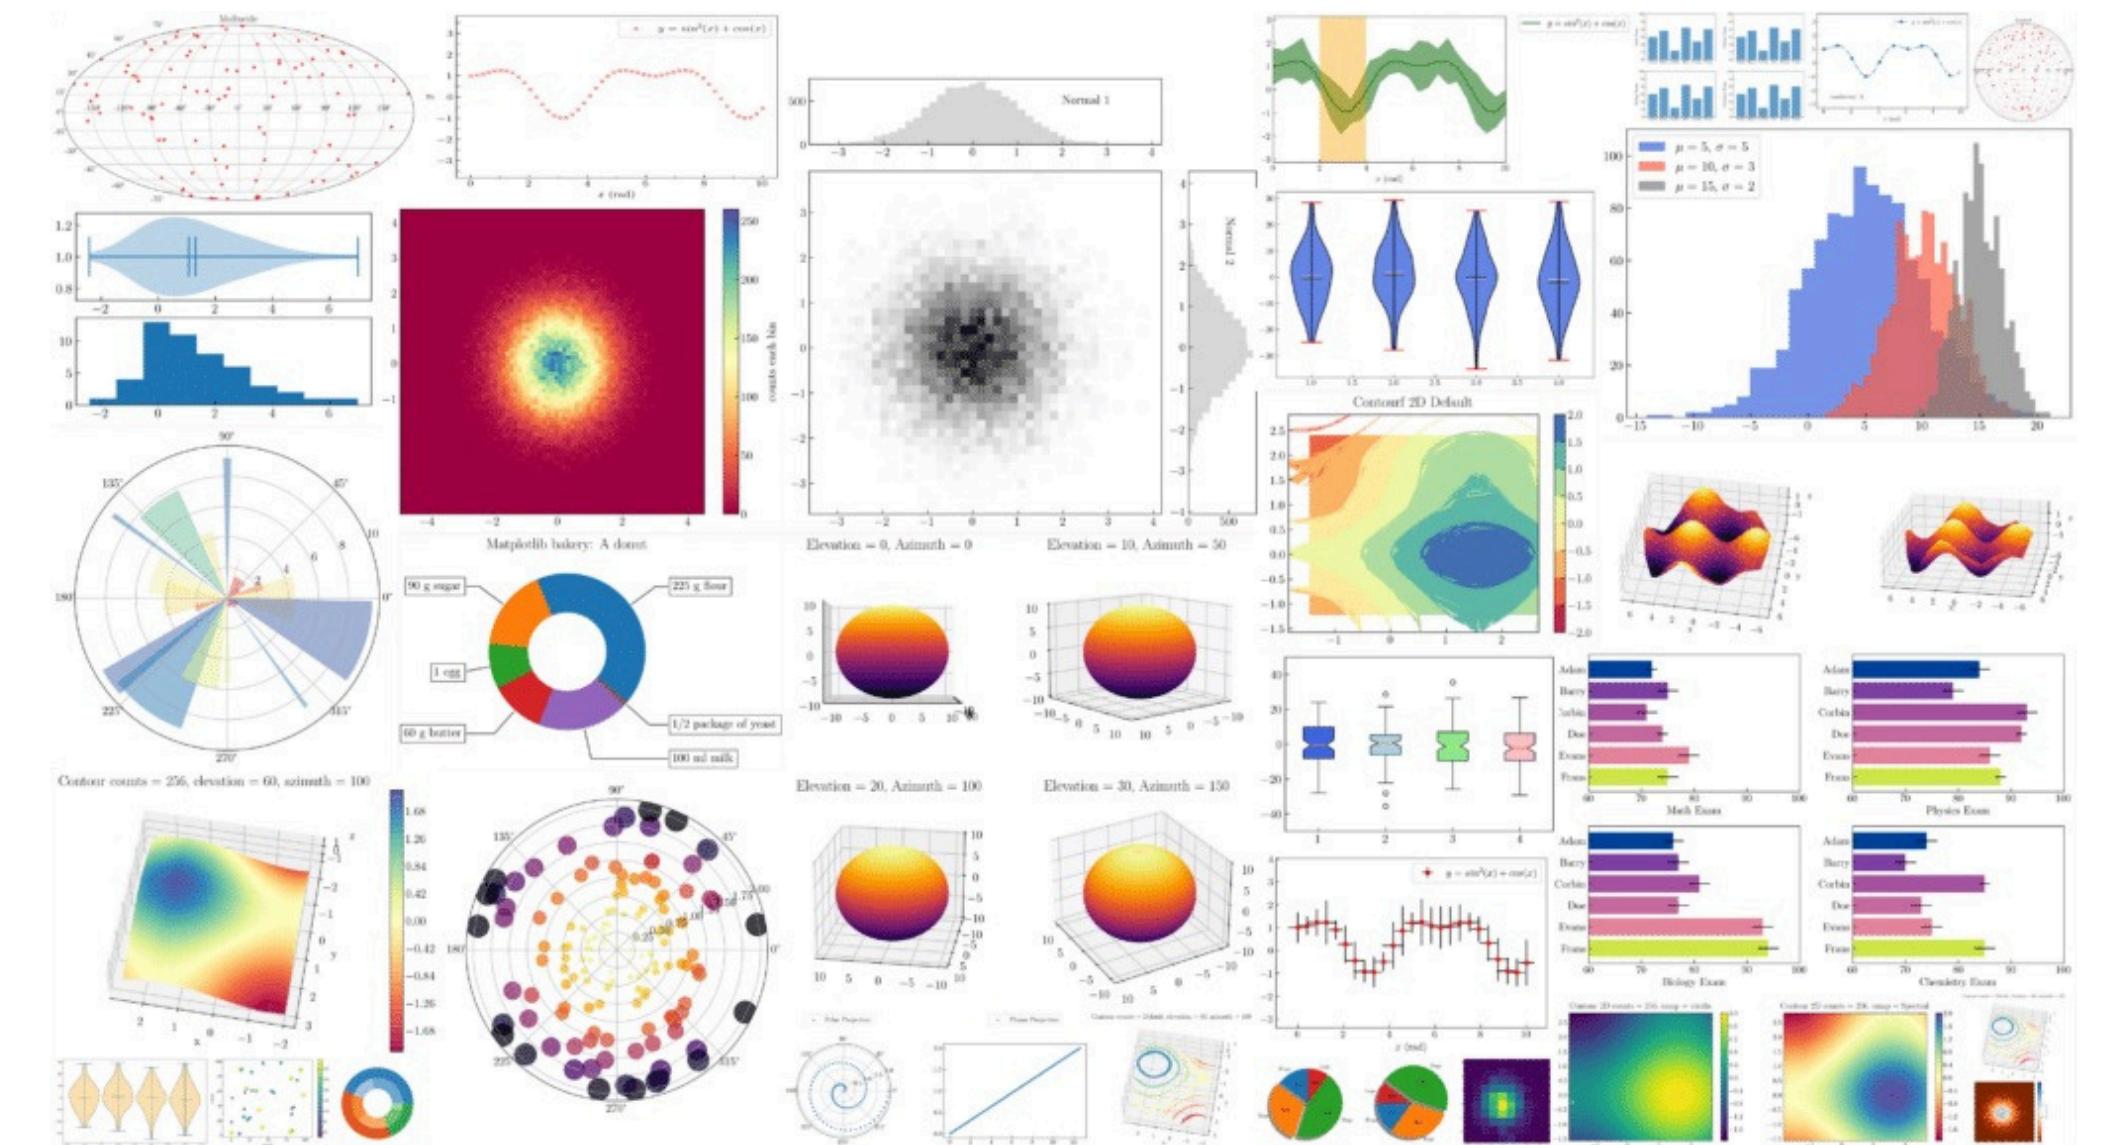

- Used to create static, animated, and interactive plots
- Works seamlessly with NumPy and Pandas
- Foundation for many other plotting libraries

Matplotlib

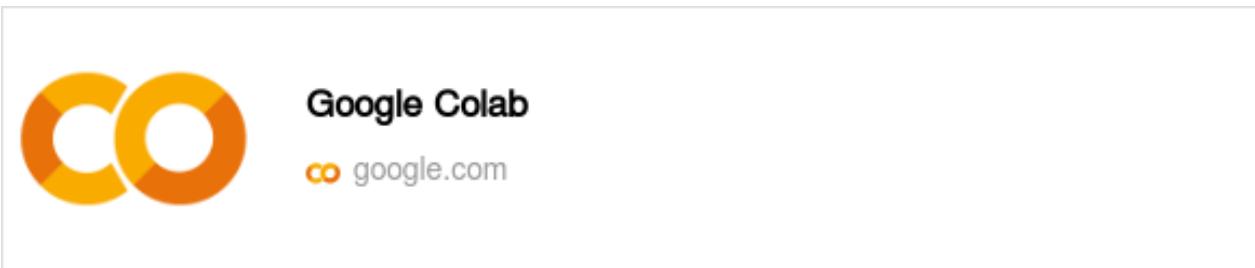

➤ Matplotlib is a Python library for data visualization

- Line Plot – trends over time or ordered data
- Scatter Plot – relationships between variables
- Bar Chart – compare categories
- Histogram – data distribution
- Box Plot – spread, median, outliers
- Pie Chart – proportions
- Area Plot – cumulative trends
- Heatmap – values across two dimensions
- Error Bar Plot – uncertainty and variation
- Subplots – multiple plots in one figure
